Chapter 1

Introduction

1.1 Introduction

Over the past ten years, academics and the general public have become interested in the intersection of work and family responsibilities (Pitt, et al., 2006). Many research on men and women have been conducted on the challenges of balancing work and home duties. While Uddin (2021) investigated the work-life balance of Muslim women in Bangladesh, Adisa et al. (2021) explored the work-life balance of British women. Furthermore, Adisa et al. (2021) investigated the Nigerian single female workers' work-life balance. One of the main causes of the noticeable rise in the number of women entering the workforce is the need to handle family responsibilities (Borah and Das, 2021). Moreover, higher education levels, free time, and social ties among women are sources of internal motivations (Bergmann, et al., 2019).

This surge in women's involvement in the workforce results in them undertaking multiple roles, not just as employees but also as mothers, wives, and caregivers for both children and other family members (Gaunt, et al., 2021). Consequently, the challenges women face in balancing work and family responsibilities intensify. The strain from this pressure complicates an employee's ability to manage and address the demands of various roles by allocating time and energy (Demerouti & Bakker, 2023). According to Moges (2022), a number of variables, including the amount of hours worked, overtime commitments, attendance, unpredictable working hours, and unmanaged work schedules, contribute to conflict in job positions. Contrarily, family role conflict is linked to factors like the number of children, lifestyle, family engagement, and childcare obligations, as well as factors like having small children, a working partner, and a large family (Clark et al., 2019).

Role conflict typically arises when individuals attempt to fulfill the demands of their work roles, which are influenced by their ability to meet family role demands, and

vice versa. This conflict, as highlighted by Soelton, et al. (2020), has repercussions on decisions related to career development, marriage, and having children.

The combination of career demands and family responsibilities can generate pressure for employees (Sarwar, et al., 2021). This stress, stemming from role conflict, can result in noticeable behavioral changes and even induce overall stress, as noted by Dodanwala, et al. (2023). Stress, defined as an adaptive response to external circumstances, manifests in physical, psychological, and behavioral deviations (Kassymova, et al., 2019). The family factor significantly influences an individual's stress levels, with family situations like conflicts, illnesses among family members, or strained relationships with parents, spouses, and children serving as major stressors for employees (Armstrong, et al., 2019). Similarly, work-related factors, including adherence to work rules (work role) and conflicts between work and family responsibilities, contribute to employee stress (Kavosi, et al., 2018).

It has been observed that individuals facing high levels of job and family-related issues experience elevated stress levels, and vice versa (Elahi, et al., 2022). Additionally, studies indicate that women are more prone to stress in the face of challenging circumstances compared to men (Uddin, 2021).

Taking the example of a female lecturer, the multiple roles she assumes may lead to stress due to role conflicts. Biron, et al. (2008) noted an increasing trend of stress among women working as lecturers at universities over the last decade, primarily attributed to the challenges of managing multiple roles. When the conflicts arising from these roles remain unresolved, they pose a threat to job satisfaction. Consequently, stress resulting from multiple role conflicts can adversely affect an individual's job satisfaction, especially when struggling to balance the demands of various roles (Bolino and Turnley, 2005).

1.2 Background of Study

When it comes to market competition, talent prioritization is essential. Most of the workers in the company are from the post-1980s and post-1990s generation (Lien,

2021). The post-1980s and post-1990s, formerly derided on the internet, are now crucial to the founding and expansion of companies in China. Compared to workers born in the 1960s or 1970s, this generation is considerably different because they were not raised in a common upbringing. Instead, they were raised in an individualized collective, which resulted in distinct personalities characterized by a dislike of restriction, a strong sense of self, a vulnerability to pressure, and a willingness to succumb easily (Liu, et al., 2023).

The post-80s and 90s place more focus on individual work success since they have higher levels of education overall and a strong desire to accomplish personal values (Li and Lu, 2014). Conventional mental stimulation methods, including praise and criticism, are no longer very effective in motivating people. As a result, attitudes toward businesses are varied and characterized by ambiguous expectations in the post-1980s and post-1990s. They concentrate on aspects including non-material incentives, such as self-perception, psychological responsibility, interpersonal relationships, work environment, and organizational commitment (Lien, 2021).

According to Kollen (2021), managing today's diverse workforce is the most challenging aspect of diversity management. Companies can no longer employ traditional management methods, and effective management is crucial to mobilize the post-80s and 90s' initiative, enthusiasm, and creativity, ultimately creating value for the enterprise (Lien, 2021). Conversely, improper management may lead to negative outcomes. Effectively addressing the generation gap, especially concerning the post-80s and 90s, is a pressing concern for many companies (Ren, et al., 2018). Reconsidering strategies and tactics in workforce construction is essential to this end. Recognizing the differences between generations can assist managers in enhancing employee productivity. Post-80s and 90s denotes the Chinese generation born between 1980 and 1999. The term "Post-80s and 90s employees" encompasses individuals from this generation who are either directly or indirectly involved in enterprises.

In contemporary times, individuals from the post-80s and 90s generation have increasingly emerged as the predominant force across various domains. In comparison to those from the post-70s and post-60s eras, the post-80s and 90s cohort enjoys

significantly improved life conditions and educational backgrounds (Xian and Forrest, 2020). Typically, post-80s and 90s teenagers are characterized by their wealth of knowledge, innovative thinking, distinctiveness, and a self-centric approach (Li and Lu, 2014). They have been exposed to comprehensive, multicultural education and have early familiarity with advanced technology.

It is widely held that the majority of post-80s and 90s employees exhibit high levels of creativity and competence (Che, 2021). However, their strong desire for success can sometimes result in a deficiency of teamwork and patience. Post-80s and 90s employees differ significantly from their counterparts in the post-70s and post-60s, rendering traditional management models inadequate for meeting the contemporary workforce's needs (Li and Lu, 2014). Consequently, there is a pressing need to establish a new management paradigm, particularly in the competitive landscape of the financial market. Niemi, et al., (2021) has emphasized that in the fiercely competitive corporate environment, the battle for talent is ceaseless, and there is an acute shortage of high-quality candidates.

People born in the 1980s and 90s typically pursue more advanced and extensive education, with some even choosing to study overseas, due to a growing economy and stable political environment. Numerous them earn degrees from globally renowned universities. They typically pursue a wider variety of interests outside of academics, such as sports, music, and the arts. People born after the 1980s and 1990s tend to be more well-rounded than those born in the 1970s and 1960s.

They are therefore more knowledgeable, have a more accepting mindset, and can tolerate more novel concepts. Employees born after the 1980s and 1990s had higher aspirations than their forebears. Furthermore, most of them are from single-child households, which might exacerbate personality traits including irrationality, a lack of cooperative skills, selfishness, and self-centeredness (Sethi, 2018).

Many who criticize post-1980s and post-1990s people claim that they lack empathy and teamwork, which makes problems at work unavoidable. Furthermore, it is a common perception that their ability to handle pressure is relatively poor. Growing up in a privileged environment with abundant resources, sufficient food, and the absence

of war, they have not faced the hardships experienced by previous generations. As a result, when thrust into the workforce and confronted with the need to independently address challenges, post-80s and 90s employees often find it challenging to shoulder the responsibilities placed upon them.

1.3 Problem Statement

Whether minor, moderate, or major, a variety of difficulties may come up at work and potentially lead to conflict (Van et al., 2019). According to Jensen et al. (2003), conflicts can appear at the individual, interpersonal, intergroup, and organizational levels. The tension that arises when work and family obligations collide is one type of role conflict that employees may experience (Bolino and Turnley, 2005). The multiplicity of roles people play in their lives gives birth to this conflict, as different roles can lead to internal conflicts. The conflict between work and family duties, where the demands of both positions cannot always be balanced, is referred to as multiple role conflict by Gutek et al. (1991).

Clatk et al. (2019) have identified two main categories of multiple role conflicts: work-to-family conflict and family-to-work conflict. Contrary to work-to-work conflict, which arises when employment requirements conflict with family time, family-to-work conflict happens when work duties conflict with family time. Tension and stress can arise when job and family responsibilities clash. Stress and multiple role conflict have been found to be strongly correlated in numerous research (Amady et al., 2017; Karimi et al., 2014). Furthermore, studies show that role ambiguity, conflict at work, and stress reduction are positively correlated (Cahaya, et al., 2020).

1.4 Research Objectives

1. Evaluate how employees' psychological capital affects their impressions of how work and family can interfere with each other..
2. Examine how management actions that support families affect employees' success on the job.

3. Examine how family members view the influence of an employee's work on their family life and learn more about the alleged disruptions to family members' private lives caused by the employee's employment.

1.5 Research Questions

1. How much of an impact does an employee's psychological capital have on how well they function on the job when work and family conflict?
2. How do supervisory actions that assist families affect employees from the post-80s and post-90s generation in terms of their job performance?
3. What effect does an employee's employment have on family life, according to family members?

1.6 Chapter Summary

This chapter offers a perceptive overview of the studies on the effects of work-family conflict on job performance, with a focus on Chinese employees from the post-80s and 90s generations. The chapter explores the changing dynamics of the confluence of work and family obligations, highlighting the difficulties that people—especially women—face while juggling many duties. The discussion explores the factors that lead to role conflict, such as childcare responsibilities, family size, and work schedule. Stress becomes a major subject as a result of juggling job and family obligations, with a focus on how stress shows up as behavioral, psychological, and physical abnormalities. A strong drive to defend personal principles and a self-centered worldview were among the distinctive traits that structured research on the impact of the post-80s and post-90s generation on the workforce. In summary, the chapter ends with a clear explanation of the research questions and objectives, laying the groundwork for an empirical investigation into psychological capital, supervisory behaviors that assist families, and family members' perceptions of how an employee's work affects their family life. In the context of China's unique post-1980s and post-1990s generation, Chapter 1 provides a thorough framework for comprehending the complexities of work-family conflict and its implications for job performance.

Chapter 2

Literature Review

2.1 Chapter Overview

Chapter 2 provides a comprehensive analysis of work-family balance and its impact on job performance. It begins by discussing the concept of balance satisfaction and emphasizing its subjective and cognitive components. This chapter introduces the Personal Resource Allocation (PRA) theory, which takes into account important elements like individual outcomes, demands, resource allocation strategies, and personal resources. The emphasis then switches to the research's prevalent focus on work-life conflict, arguing in favor of a more all-encompassing viewpoint that takes good work-life enrichment into account. The chapter also looks at psychological capital and the effect supportive supervisory practices have in work-family conflict. The importance of job performance is explained in detail, along with the variables that affect performance levels. Proposed hypotheses in the chapter's conclusion predict a considerable detrimental impact on the workplace performance of China's Post-80s and Post-90s Generation Employees from both work-family and family-work conflict.

2.2 Theory

2.2.1 Work–Family Balance Satisfaction

According to Sarwar et al. (2021), balance satisfaction is the whole satisfaction that results from an evaluation of one's capacity to meet the demands of both work and family obligations. People can assess certain aspects of their lives based on satisfaction variables without being constrained by conventions, standards, or research-imposed criteria (Hayward, 2014). As a result, satisfaction ratings capture subjective opinions mostly based on self-centered expectations and represent an individual's in-depth assessment of certain life components, such as family, work, finances, and overall life (Sholihin, et al., 2022).

In a similar vein, balance satisfaction takes into account an individual's emotional and cognitive assessment of their existing work-family balance (Wayne, et al., 2021). The cognitive component consists of people's evaluations of the resources that are available and distributed in a way that supports the effective integration of responsibilities between the two domains. The appraisal of the work-family balance that results from this cognitive assessment is affect-based and ranges from positive emotions such as contentment and satisfaction to negative emotions such as discontent and dissatisfaction (Li, et al., 2020).

Similar to other attitudes, balance satisfaction is influenced by both internal and external factors. However, it represents internal studies of the external environment utilizing predefined standards during the assessment process (Sarwar, et al., 2021). Even under similar circumstances, such as spending more time at work and less time at home, two employees' degrees of balance satisfaction may differ significantly (Bellmann and Hubler, 2021). Therefore, it may be concluded that situational antecedents and human traits like as personality, values, age, gender, and so on are significant in determining balance satisfaction.

Research examining the consequences of balance satisfaction has discovered connections between it and a range of outcomes related to performance and well-being (Yoon, et al., 2022). Employee job happiness, family contentment, organizational commitment, and family success are all favorably correlated with balance satisfaction (French et al., 2020). It was found to be a personal resource that was positively correlated with workers' creativity in a study by Ng et al. (2021). Even in the face of a strained relationship with one's boss, the study indicated that creativity was highest when balancing satisfaction was high and time pressure was low.

Balance satisfaction was found to be a positive predictor of supervisor-directed organizational citizenship behavior (OCB) and emotional organizational commitment (AOC) in a non-Western study by Sarwar et al. (2021). The study also showed that the association between "family-supportive paid leave" and AOC, "family-supportive supervision" and "supervisor-directed OCB," and AOC was mediated by balance satisfaction. These strong empirical results about the usefulness of this attitude in forecasting favorable results emphasize the significance of examining its formation,

especially in light of the fact that the literature on this construct is still in its infancy and is comparatively scarce when it comes to academic faculty.

2.2.2 Personal Resource Allocation (PRA) Theory

The four main components of the PRA framework are individual outcomes, demands, resource allocation strategies, and personal resources. Previous studies on work-life balance, such those by Ortiz et al. (2023), Fan et al. (2021), and Wang et al. (2019), have given considerable attention to each of the four components. These components—stressors, demands, work-life conflict, and role ambiguity—have all been well studied, despite differences in terminology. In contrast to previous work on the topic, the PRA framework combines data from multiple sources and suggests that the real definition of the ideal "work-life balance" is the efficient application of one's own resources in all facets of one's life. By employing this approach, scholars can transcend dogmatic assumptions like "life at work is bad, life at home is good," and instead get a deeper comprehension of the interactions between people and their surroundings that lead to both favorable and unfavorable individual outcomes. It achieves this by looking at life events from a wider perspective rather than concentrating just on work or family circumstances.

The Conservation of Resources (COR) theory by Grawitch et al. (2010) and other self-regulation techniques described by Morrison et al. (2022) serve as the foundation for the Personal Resource Allocation (PRA) framework, which is a thorough conceptualization. Fundamentally, the PRA framework explores the complex dynamics of people navigating their everyday lives within the limitations of limited resources.

To put it simply, people bring a finite set of resources to the table, which are called personal resource inputs. These resources include time, energy, psychological reserves, and other intangibles in addition to tangible goods. People are always allocating their limited resources, choosing where to direct them, as they deal with demanding situations in all areas of their lives.

Understanding the effects of these resource allocation choices is central to the PRA framework. People eventually find themselves with fewer resources available to face new challenges after resources are committed to meeting certain demands. This fundamental trade-off ends up being a major determinant of people's general happiness and well-being.

When people believe they have what it takes to successfully manage the demands in their lives, the positive outcomes found in the PRA framework materialize. This view involves two aspects: the subjective conviction that one has sufficient control to allocate resources according to one's desires, and the actual ownership of resources. Furthermore, a crucial element of favorable results is the person's satisfaction with their resource allocation, which reflects a personal feeling of fulfillment and balance.

The PRA framework provides a comprehensive viewpoint on the management of personal resources in response to demands in life by seamlessly integrating several theoretical frameworks. It does this by not operating in isolation from other frameworks. It recognizes the range of demands people encounter in their pursuit of different life goals, whether they be in the social, professional, or personal spheres. As a result, the PRA framework acknowledges that the dynamics of resource distribution are dynamic and sees this resource management as a personal and ongoing activity.

Additionally, at every phase of this resource allocation process, the PRA framework pinpoints possible intervention points. These intervention moments are tactical windows of opportunity to improve well-being, optimize resource management, and lessen the adverse effects of resource depletion. The identification of these intervention sites highlights how useful the framework is in providing direction for interventions and support systems that are customized to the particular difficulties that each person has while allocating resources.

Essentially, the PRA framework serves as a dynamic and nuanced lens through which we can see how people struggle to manage their own resources in the face of life's demands. Drawing from well-established frameworks like as COR theory, it not only offers theoretical depth but also offers practical insights for interventions that might

positively influence people's processes for allocating their resources, leading to improved well-being and life satisfaction in the end.

The PRA framework, as presented by Ngbea (2019), aims to elucidate the interdomain transitions of personal resources in order to comprehend the ways in which work and nonwork demands impact work-life conflict. As a result, this conflict is detrimental to one's subjective well-being as well as one's professional growth. The fundamental premise is that individuals must arrange their limited personal resources—such as time and energy—to satisfy demands in a variety of spheres of their existence. People must decide how, when, and where to allocate these finite resources in order to achieve these needs Bower (1972). A lot of outcomes that are significant for both personal and professional life are influenced by this distribution.

One of the primary assumptions of the PRA framework is that people are compelled to devote the majority of their limited resources to the work domain while they are attempting to meet the demands of their jobs (Wan, et al., 2022). When resources are allocated, there are less of them left to handle requests from the nonwork domain, which leads to people believing that work interferes with personal time. In the end, these disruptions affect professional, personal, and occupational results (Decarlo, et al., 2019).

Moreover, the PRA framework implies that people differ in their tactics and preferences for allocating resources. Individuals are predisposed to different values and goals based on their personality traits (Tabernero et al., 2020), which affects how resources are allocated. Therefore, when faced with occupational stresses, personality factors may potentially affect how individuals allocate their limited resources to work and nonwork domains (Huo and Jiang, 2023).

2.3 Work life conflict

Although few scholars—Zhang et al., 2021; Powell et al., 2019—have highlighted the benefits of work-life contact, the majority of studies have concentrated on the issue of conflict. The majority of research conducted nowadays takes a reductionist stance in

an effort to ease conflicts between work and personal life. Studies evaluating the impact of work-life balance initiatives on the outcomes of individuals and organizations, for example, often emphasize the role that conflict plays in the "work–family interface" (Wayne, et al., 2022). The understanding of how the work role could help larger life domains may be severely limited by the empirical focus on conflict and its concern on lowering the negative repercussions of work on life, rather than supporting labor that optimizes its positive role.

Based on the idea that work gets in the way of family time, a lot of research on work-life balance, including modern conceptualizations, posits that work is a necessary evil that supports activities outside of work. Within the context of organizations, this presumption informs research that views work-life balance initiatives as ways to mitigate the negative consequences of non-work obligations, frequently without yielding immediate advantages for the company (such as paid time off or daycare benefits). For instance, the Bloom, et al. (2009) measure of work-life practices includes 19 behaviors, 13 of which center on workplace advantages (such as paid time off, daycare, and vacation time) that are better suited to managing one's personal life than work-related responsibilities. Positive psychology has become more prominent in the broader field of psychology as a result of this reductionist viewpoint. Even though lowering negative consequences has been the subject of many research, attaining overall well-being necessitates discovering elements that support personal development and growth in both the environment and the individual.

Within the context of organizations, research on work-life balance typically focuses on conflict and ignores facilitation. Samaranayake (2019) included "work–family conflict" in the headline of even their most current review on the subject, but they mainly ignored "work–family enrichment." Although "enrichment" is referenced in passing throughout the study, conflict is still the main focus—133 times as many mentions of "conflict" as there are of "enrichment." This emphasis suggests that minimizing the negative effects of conflict should take precedence over fostering the beneficial effects of enrichment in both research and organizations. As these aspects may not always overlap, the PRA framework—which is explained below—aims to promote greater research into the reasons why workers find fulfillment and flourish at the intersection of their work and non-work lives, rather than focusing just on

strategies to reduce work–life conflict. Furthermore, the framework seeks to provide businesses with a means of evaluating different intervention points in light of the particular requirements of their workforce.

2.3.1 Psychological capital-Work family conflict

A conflict between the roles of work and family is referred to as work-family conflict. Zhang and Bowen (2021) claim that this conflict develops when performing a job function makes it difficult to meet obligations to one's family. They draw attention to the fact that stressful work schedules, stress from one position influencing another, and actions deemed proper in one context but inappropriate in another can all contribute to work-family conflict. Work-family conflict arises when there is an imbalance in the demands made by work and family, which makes it difficult to fulfill commitments in both areas (King, et al., 2012). Conflict like this is linked to psychological issues in workers..

The psychological and structural disruption brought on by lengthy workdays was examined by Gorgievski et al. (2019), who emphasized that working long hours saps energy at home. The study introduces the idea of work-family fit and discusses how support services and work-family conflict affect working individuals' mental health. Wives of top administrators felt that their husbands' work expectations affected their families and created tension in communication, according to Akanji et al. (2020).

Lu (2007) looked into work-family conflict among Taiwanese working women and discovered a substantial correlation between it and higher levels of stress, more severe physical problems, and decreased levels of job and family satisfaction. Differing perspectives on the work-family dynamic can be detrimental to emotional health. There is a persistent positive link seen in research findings between workload, prolonged work hours, and work-family conflict.

An individual's propensity to feel a lot of distress, worry, despair, and other negative emotions is known as negative affectivity (NA). In their investigation of the connection between NA and work-family conflict among senior civil officials in

Hong Kong, Stoeva et al. (2002) discovered that those with higher NA levels encounter more problems in both directions than those with lower NA levels. A study conducted in Toronto, Canada, found that anxiety and sadness were linked to home-to-work conflict in both male and female employees. Females tended to be more anxious about spillover than males did, even after adjusting for a number of variables (Scheieman, et al., 2003).

The association between the duration of the workweek and faculty discontent with work overload was investigated in a 1988 national survey of post-secondary instructors (Aslam, et al., 2011). Despite the fact that lengthy hours led to a high burden that dissatisfied professors, they also enhanced research productivity. High levels of work-family conflict were linked to poor performance as well as a decline in both family and professional well-being, according to Obernovic et al. (2020). Determining possible work requirements for academic staff members that complement their personal lives is a formidable obstacle.

"Work-family spillover" refers to the extent to which one's activity in one area affects one's involvement in the other. Positive and negative work-family spillover are the two varieties. Various types of interference and conflict between work and family are examples of negative spillover. Conversely, productive work-family balance, resource improvement, and other similar practices are examples of positive spillover (Wayne et al., 2017).

The impact of work-family conflict was examined by Khan, et al. (2022) in relation to work and family role aspects. They looked at measures of psychological well-being in males and females working for themselves as well as those hired by organizations. They discovered that those working for themselves had more freedom to choose their own schedules and were therefore more involved in and satisfied with their jobs. They did, however, also report lower family happiness and more conflict between work and life.

Female workers were more likely than male workers to report positive spillover from work to home, according to Grzywacz et al. (2002), who studied work-family spillover and daily reports of work and family stress in the adult labor force. A lower

risk of negative work-family spillover was associated with schooling. In a study including 203 teachers, Lin et al. (2022) found that organizational citizenship behavior (OCB) was negatively connected with work-family conflict but favorably correlated with job satisfaction, organizational commitment, and work-family culture. The findings showed how important it is for schools to support a culture that values work-family balance.

2.3.2 Family-supportive supervisory behaviors- Family work conflict

When a person's work-life balance is disrupted by taking on family duties, it's referred to as family work conflict. The degree of friction between an individual's personal and professional lives is determined by their fundamental beliefs about their responsibilities in the work and home spheres. There are two aspects to this conflict: the work-family conflict happens when work gets in the way of family life, and the family-to-work conflict happens when work gets in the way of family matters.

Ohu et al. (2019) found that parents report higher levels of work-family interference. Working hours, family expectations, time spent on child care, and professional flexibility are some of the elements that contribute to this interference. The number and age of children as well as weekly working hours are the main elements that cause work-family role strain for persons who have jobs and families (Bai et al., 2021). Working parents sometimes found it difficult to juggle the responsibilities of their jobs and their families, especially if their children were in preschool.

Furthermore, working mothers of preschool-aged children experienced greater pressure than men to manage their obligations as a family and at work, according to Molina's research from 2021. Taking care of work-family conflicts at work was the main focus. Day et al. (2006) discovered that the existence of children had no effect on spouse employment in terms of work-family interference. A positive correlation was observed between the number of children living at home and family-work conflict, as per Ruppanner's (2013) findings.

According to Santoro (2021), people were less content than those who could match their behavior in the home and workplace with their principles. To reduce role conflict, organizations have instituted family-friendly policies including job sharing and flexible scheduling. According to Frye et al. (2004), the availability of family-friendly policies reduces work-family conflict and is associated with the usage of family benefits and benefit availability. Improved family life and fewer work-family tradeoffs were reported by employees in work settings that support families.

Family-work conflict was preceded by stressors such demands from parents, time spent on housework, and lack of spousal support (Michel et al., 2011). When the organization and an employee's family have the same beliefs, there is reduced likelihood of work-life conflict. Conflicting values between people and important family members or between people and organizations, according to Obrenovic et al. (2020), cause tension between expectations from work and family.

Work-family conflict eventually results in dissatisfaction with one's job and life since it prevents the realization of core ideals in both the work and family realms. Breugh and Frye (2008) evaluated a model for work-family conflict and family-work conflict using job and family happiness as dependent factors and supervisor support, amount of work hours, childcare requirements, and family-friendly policies as independent variables. Their research showed a relationship between supervisor support, family-work conflict, and childcare obligations; these factors were all linked to lower levels of job and family satisfaction. When childcare obligations cause schedule conflicts with work hours, the chance of work-life conflict increases.

2.3.3 Job Performance

Sembiring et al. (2020) emphasized the significance of work performance, a subject that receives great attention in the human resources area on a regular basis. When employees are unable to adapt, their performance is likely to deteriorate at work. Numerous issues, including mismatched tasks, a lack of acknowledgement, disorganized deadlines, and little possibilities for rendering opinions and providing

suggestions, contribute to this decrease. All these elements have the potential to significantly affect how well employees perform their jobs.

According to Chaudhary (2020), completing responsibilities at work effectively and utilizing the resources at hand constitutes job performance. It is a common metric for evaluating how well employees perform on tasks related to their job responsibilities. This implies a close relationship between work performance and performance ratings.

Murphy (2020) distinguished three methods for assessing performance. In the first, metrics such as sales volume are used to evaluate performance in relation to production. In the second strategy, managers or supervisors evaluate each employee individually's performance. The third method, which employs self-ratings and self-appraisal, is seen as superior than the others. This approach is advantageous since it allows employees to freely define their own goals with the use of self-evaluation.

In the workplace, high performers typically have an easier time moving up the ranks and have higher opportunities for advancement than low performers. According to the research model proposed by Ogbonaya et al. (2019), the effort and ability of employees determine how well they do at work. They offer a novel concept in which effort is viewed as an input into the task and job performance as the result of one's efforts. Generally speaking, an employee's ability to successfully carry out their job duties is correlated with their job performance. Good performance means that duties are satisfactorily performed and there is less chance of turnover. On the other hand, workers who perform poorly are frequently unhappy in their positions, which increases their propensity to leave.

2.4 Hypothesis Proposed

2.4.1 Work family conflict and Job performance

When there is conflict between the domains of work and non-work, it becomes abnormal to attempt to achieve work-life balance. According to Raisinghani et al. (2014), work-family conflict is a prerequisite for work-life balance. According to Adisa, et al. (2021), there should be as little role conflict as possible between a

person's family and work environments. This will affect how well work and life balance out. When people get married, they have an obligation to their families. The absence of role conflict indicates that they have achieved work-life balance when they handle their responsibilities both at work and in the family with effectiveness.

According to Annan (2020), there is a negative correlation between a person's ability to manage work and life and the demands of their employment. professional and life are out of balance when an auditor's professional obligations take precedence over their responsibilities to their families. It is practically impossible for auditors to attain work-life balance when they are faced with work-family problems. Work-related obligations that impede an individual's capacity to fulfill familial commitments are referred to as family interference with work. Therefore, it could be challenging for auditors who are stressed out by family responsibilities to fulfill their professional responsibilities. Consequently, auditors are unable to devote all of their focus or effort to their work.

Work-family conflicts can persist for a long time and negatively affect both individual and company productivity if they are not appropriately resolved. conducted a thorough study, with differing degrees of effectiveness, of other studies examining the relationship between work-family conflict and workers' job performance. Since additional research supported the same findings, the evidence was equivocal. Recent investigations have also reported conclusive outcomes.

Yusuf et al. (2020) performed research among bank employees in Indonesia and private sector bank employees in the Jammu and Kashmir region, which highlighted the detrimental effects of work-family conflict on employee job performance. In contrast, a study conducted by Khan et al. (2020) on frontline employees of retail banks in Turkey indicated that work-family conflict had non-significantly detrimental consequences on job performance. Furthermore, Tewal, et al. (2021) found that work-family conflict significantly improves job performance in their research of dual-career couples in Jabodetabek.

Despite the inconsistent nature of the relationship between work-family conflict and work performance, the hypothesis proposed in this study remains:

H1: Work-family conflict has a significant negative effect on job performance of Post-80s and Post-90s Generation Employees in China.

2.4.2 Family work conflict and job performance

The idea of work-family conflict has led several scholars to assert that conflicts between work and family obligations have a major and detrimental influence on marital, family, and job satisfaction (Orellana, et al., 2023). Burke and associates (2013) conducted tests on front desk staff at three, four, and five star hotels in Ankara, Turkey, to determine the negative impact of family-work conflict on job satisfaction.

Furthermore, research has shown that the tension between obligations to one's family and career negatively impacts one's emotional state of mind, physical well-being, and general sense of happiness with life (Dorenkamp, et al., 2019). As such, there is a correlation between this conflict and a decrease in worker performance and production. For instance, when a worker's personal problems interfere with their work, it might cause them to waste time and become distracted from their duties. People might therefore need to modify their schedules in order to balance the competing demands of job and family.

Psychological interference is another factor to take into account. It is defined as the "transfer of job-generated moods to the family domain". This phenomena may have an effect on an employee's energy and attitude at home, which may result in role conflict and lower productivity at work. According to Benlian (2020), home-to-work overflow is the encroachment of work-related obligations and family-related ideas, leading to employee stress.

Moreover, employees who struggle to allocate their time to meet family obligations are likely to experience a heightened level of disruption not only at home but also in the workplace. Given the paramount importance of both family and work in individuals' lives, particularly for adults, these conflicts are ultimately poised to yield significant and unfavorable consequences on either family or job satisfaction. Thus, building on these rationales, the second hypothesis is as follows:

H2: Family work conflict has a significant negative effect on job performance of Post-80s and Post-90s Generation Employees in China.

2.5 Conclusion

A detailed knowledge of important theoretical frameworks and concepts has been offered by the literature study in this thorough investigation of work-family balance and its effects on job performance. The first section of the chapter defined balancing satisfaction and discussed its many facets, including the impact of environmental and human factors. With its incorporation of personal resources, demands, resource allocation tactics, and individual outcomes, the Personal Resource Allocation (PRA) theory became an important framework. PRA emphasizes the dynamic process of managing personal resources in response to demands across multiple domains, and is based on the notion of Conservation of Resources. The conversation then turned to the research's current emphasis on work-life conflict and urged a change to a more all-encompassing viewpoint that takes good work-life enrichment into account. Examining psychological capital in the context of work-family conflict revealed the complex interactions that exist between negative affectivity, long work hours, and the structural and psychological interference that employees must contend with. The delicate relationship between work and family commitments is highlighted by family-friendly supervisory behaviors and their impact on family-work conflict. These behaviors also highlight the importance of family-friendly policies in reducing conflict and improving overall satisfaction. The examination of work performance emphasized its importance in human resources by describing the elements that lead to improved or decreased performance. The suggested hypotheses, which predicted a strong negative impact of work-family conflict as well as family-work conflict on the job performance of Chinese employees belonging to the Post-80s and Post-90s generations, provided a layer of specificity to the review. The chapter concluded with a summary of the important lessons learned from the literature, setting the stage for more empirical research in later chapters. This analysis highlights the necessity for a comprehensive strategy that takes into account both conflict and enrichment features, especially in the particular context of academic faculty in China, in addition to making a valuable contribution to the field of work-family balance research.

Chapter 3

Methodology

3.1 Chapter Overview

This chapter provides a comprehensive framework for the study, beginning with the significance of a well-crafted research design and an exploration of descriptive research purposes. The research philosophy section introduces positivism and interpretivism. The decision to adopt a positivist perspective for investigating work-life conflict and job satisfaction in the retail sector is justified. The chapter details the research approach, emphasizing the use of quantitative methods and the exclusion of qualitative approaches due to reliability concerns. Probability sampling, specifically stratified random sampling, is chosen as the research strategy to ensure representation. The section on data collection and instrumentation emphasizes the importance of a well-structured survey for robust results, discussing aspects of internal validity, reliability, and questionnaire construction. The research location is outlined. Ethical considerations prioritize participant confidentiality, with a commitment to anonymity throughout the study.

3.2 Research design

A research design is a methodically constructed plan intended to handle variance and respond to the research topic. According to Farrugia et al. (2010), the main goal of any research is to either test the research hypothesis or provide a response to the research question. Control of variance involves the consideration of factors that could systematically influence the research outcomes or complicate the interpretation of results, even though they are not inherent to the research question or hypothesis. The term "variance" encapsulates the inherent variability in data points, and controlling it becomes imperative to maintain the internal validity of the research. Variances can arise from a multitude of sources, including extraneous variables or confounding factors that, though not integral to the primary research question or hypothesis,

possess the potential to systematically influence research outcomes. Therefore, the research design must be astutely crafted to identify, account for, and if possible, neutralize these variables, ensuring that the observed effects can be confidently attributed to the manipulated independent variable rather than external influences. Researchers are need to carefully take into account any aspects that can potentially muddy the interpretive landscape of the results in this complex dance with variance. This diligent method goes beyond simply identifying confusing variables; it also entails taking the initiative to proactively address and regulate these variables beforehand. By doing this, the research design serves as a defense mechanism, strengthening the study against the sneaky influence of unrelated factors that could jeopardize the validity and generalizability of findings.

Furthermore, there is no one-size-fits-all approach to variance control. Every research project has its own special set of difficulties and complexities, necessitating a customized approach to methodological design. The peculiarities of their particular field of study, the nature of the research topic, and the complexities of the factors at play are all things that researchers need to be aware of. As a result, creating a study design becomes as much an art as a science; it's a dynamic, adaptable process that calls for insight and mental acuity.

The scientific community relies heavily on descriptive research because it provides a comprehensive method for looking into and comprehending a wide range of occurrences. The literature on this topic presents a range of goals and concepts that together expand the use of descriptive research. Above all, one of the key goals is to accurately and methodically depict the features and information that are inherent to a community or a particular place of interest. This section of descriptive research entails a comprehensive analysis with the goal of offering a comprehensive grasp of the nuances that characterize the topic being studied.

Descriptive research is also useful for providing a succinct description of the traits connected to particular objects, circumstances, or populations. It is an instrument for deciphering new meanings, characterizing the situation at the moment, identifying recurrent themes, and organizing this kind of data. This characteristic highlights how descriptive research is dynamic and can reveal nuances in the subjects under

investigation. The third objective is to carefully watch, describe, and document information as they come to light spontaneously, with a focus on the method of portraying the traits of individuals, circumstances, or groups. This feature draws attention to the observational component of descriptive research and emphasizes how crucial it is to capture events in their original condition in order to present an accurate depiction of the subject matter.

Additionally, descriptive research is necessary to identify relationships or correlations between particular variables. This goal explores the analytical side of the approach, where researchers look for and clarify the relationships between various components inside the parameters of their investigation. Finally, descriptive research is a useful technique for responding to inquiries concerning current occurrences. This implies that it is amenable to contemporary inquiries and that the research process is dynamic, permitting inquiry and analysis in real time.

When combined, these ideas offer a convincing defense of the objectives of descriptive research. The essential element of this study design is the accurate and systematic description of "something" or "someone." "Something" can refer to an event, a phenomenon (behavioral, psychological, or cultural), or a characteristic (e.g., attitudes, feelings, or voting tendencies). In the meantime, "someone" might refer to a person, a community, or a group. A single variable of interest, such as the frequency of nausea in a particular group of chemotherapy patients, may be the subject of research, or it may seek to identify correlations between two or more variables.

3.3 Research Philosophy

According to Abu (2019), research philosophy represents the perspective and belief system guiding the conduct of research and the relationship between theories and collected data. Various definitions and categories of research methods exist, often overlapping. Positivism and interpretivism are the two most recognized research philosophies, and ontology and epistemology are the main frameworks for thinking about research philosophy.

Positivism, is associated with the sciences, particularly natural science, emphasizing an objective and external reality. In contrast, interpretivism, is seen as an approach to social science, asserting that reality is subjective and socially constructed, varying for each individual.

Ontology, discuss the nature of reality, addressing questions about what exists and how it exists. Positivists hold that there is one objective reality external to the observer, while interpretivists argue that reality is socially constructed and varies among individuals. Various ontological perspectives, such as realism, materialism, critical realism, idealism, and relativism, are acknowledged Bisman (2010). Concerning epistemology, interpretivists contend that knowledge is acquired through individuals' social constructs, formed through observation and opinions. On the other hand, positivists assert that knowledge is measurable through observable phenomena.

Auguste Comte, a French philosopher, is credited with inspiring the positivist paradigm in the study of social reality. Comte believed that the best ways to comprehend human behavior were via observation and reason, and that true knowledge could only be obtained by sensory experience through experimentation and observation. Positivists hold that properties of reality may be measured objectively, without reference to the researcher or their tools. It basically says that knowledge is quantifiable and objective.

Scientific methods are employed by positivist thinkers to systematize the process of knowledge generation, utilizing quantification to enhance precision in describing parameters and their interrelationships. The primary focus of positivism is considered to be the uncovering of truth and its presentation through empirical means (Fischer, 1998). Siponen, et al. (2021) further explains that scientific knowledge is considered by positivism to consist of facts and reality to be viewed as independent of social construction.

In positivist research studies, a 'objectivist' viewpoint can be used for investigations involving a constant and unchanging reality. Realist ontology, which embraces the idea of an objective, real reality, is involved in this. The detached epistemological position is predicated on the idea that judgments and assertions made by individuals

are either accepted as true or incorrect. According to this viewpoint, knowledge is something tangible and attainable, which makes it acceptable to use techniques that require altering and controlling reality.

Given that the impact of work-life conflict on job satisfaction is investigated by this research and aligns with the positivist paradigm, it implies a commitment to an objective, realist perspective, and a belief in the measurability of phenomena through empirical methods.

3.4 Research Approach

In the exploration of existing literature concerning work-life conflict (WLC) and job satisfaction within the retail sector, the decision has been made by the author to adopt the positivist perspective as the most beneficial approach for addressing the research questions. The collection of necessary data will be carried out through the utilization of the quantitative approach, which has been most commonly employed in previous studies and research endeavors.

The positivist approach is thought to be more conventional and offers more understanding in a precise, fact-based manner. Large quantitative data sets are highlighted because they provide a broad picture and a veracity that can be investigated and tested. The objectivity of positivist research is to answer the question that "Positivist research studies an objective world that is stable and predictable." The stable and predictable nature of the external world, created by social constructs, is acknowledged. As the researcher, the undertaken study is approached from the role of an objective analyst of the external world within this research area. Positivism's lack of flexibility and disregard for random and unexplained phenomena, along with the observation that positivism tends to be generalistic and challenging to apply to specific situations or areas.

The positivist research ideology is adhered to by the quantitative research and design used, which makes use of particular and highly structured data collection techniques. The data, which is mostly drawn from large groups, is used to test theories by looking

for positivist-perceived distinctions and regularities. In response to the literature review, the author gathered data by asking carefully constructed survey questions about a range of characteristics with the goal of using experience data to produce substantiated proof.

The quantitative research conducted in this study revolves around the specific variables identified in the literature review, examining their interconnections and individual impacts. Numerical measurements, employing various scales, are applied to these variables, and the results are analyzed and presented in the report's analysis chapter. To obtain a general and overall perception of the data and results, the author opted for probability sampling, leveraging access to a specific sample within the retail sector.

The author made the simple choice to forgo the qualitative research approach. Although opinions, experiences, and beliefs can be best explored through qualitative research, the data and feedback produced are seen to be less accurate than those from quantitative research (Zyphur, et al., 2020). Even though fewer people use qualitative research, the data it produces is extremely difficult to generalize and frequently impossible to do so.

3.5 Research Strategy

Probability sampling and surveys stand as widely employed research strategies for acquiring specific data. A four-stage process for probability sampling. First, selecting a pertinent sampling area linked to the research objective, exemplified in this report by focusing on employees who have worked. Second, determining an appropriate sample size, the sample cases/participants under fifty should be excluded. Larger sample sizes decrease the likelihood of error, contributing to more accurate and reliable findings; in this study, the author secured a sample size of 150 participants. Third, choosing an optimal sampling technique and sample from five discussed methods. The author opted for stratified random sampling, dividing the population into smaller, specific groups (strata), such as retail employees. This method allows data collection based on personal experiences and attributes, offering benefits of

straightforward and accessible strata, along with cost-effectiveness when dealing with specific and accessible strata. Finally, verifying that the sample is representative ensures the collected data aligns with existing knowledge about the population of retail employees.

3.6 Data collection and instrumentation

Quantitative research and survey research methods play a pivotal role in gathering general data, commonly employing self-completion surveys available in both hard copy and online formats. These surveys are designed to be answered independently, without the need for supervision unless explicitly required. In the context of a specific study, a survey research strategy was chosen, featuring a self-completion survey divided into two sections, each containing ten questions or more. Respondents were given the flexibility to opt for either a hard copy or an online version of the survey for their convenience.

Emphasizing the importance of a well-structured survey, there is a need for researchers to ensure that the survey effectively collects the necessary data, guaranteeing reliability and consistency. Factors such as finances, distribution, participant availability, and time are acknowledged as potential influencers on the survey process, demanding careful consideration. Jaeger, et al. (2022) supports this perspective, highlighting the substantial effort required to create a comprehensive questionnaire that addresses research questions and garners a satisfactory response rate. They note the relative ease of questionnaires compared to interviews, offering more generalized and precise data due to specific questions and a large sample.

Woolcock (2019) highlight the critical nature of internal validity and reliability in questionnaires. Internal validity is intricately tied to the ability and structure of questions to measure the intended aspects of research, rather than flaws in the design. Story, et al. (2019) expands on internal validity and reliability, emphasizing the importance of mutual understanding between the researcher and respondent regarding question interpretation.

In the construction and validation of questionnaires, Obilor, et al. (2022) outline three key aspects to consider: content validity, ensuring comprehensive coverage of relevant aspects; criterion-related validity (predictive validity), assessing the strength of questions in predicting outcomes; and construct validity, evaluating the extent to which measurement questions truly capture intended constructs.

Beyond validity, the authors discuss the reliability of questionnaires, acknowledging its importance in achieving consistent findings across different times and participants. While not as crucial as validity, reliability allows researchers to obtain dependable results amid varying circumstances and individual opinions.

3.7 Research Location

The main goal of the study is to comprehend how, in the Chinese context, the interaction between work and family obligations influences the professional performance of members of different generational cohorts. Targeted surveys will be used to gather data from Chinese professionals; participants will be reached through a variety of platforms, including social media. The objective is to gather important insights about the work-family conflict experiences of employees from the post-1980s and post-1990s generation and how these experiences affect their performance at work.

3.8 Ethical Concern

Preserving secrecy was the principal ethical concern for the participants and the main emphasis of the author. Every participant filled out the survey voluntarily and on their own. The survey did not ask for respondents' identities, and to further protect anonymity, each respondent's age was not asked but instead was grouped into age ranges. All demographic inquiries were made clear in the cover letter that opened the survey, stating that no private information was required, not even the names of participants or their employers. At the organization's request, the name of the organization was purposefully suppressed and will not be revealed at any point in this report. The organization and any participant can request access to the data results,

even though the report containing the gathered data and outcomes will not be made public.

3.9 Summary

To put it briefly, the research emphasizes objectivity and empirical methodologies while navigating the embrace of positivism. The study methodology is positivist in nature, utilizing quantitative techniques because of their accuracy and applicability. Representation is guaranteed by probability sampling, more especially by stratified random sampling. Surveys are preferred over qualitative methods due to their ease of generalization and reliability. The research location is determined by the study's emphasis on comprehending work-family conflicts among China's generational cohorts. Participant confidentiality is given priority by ethical considerations, and anonymity is emphasized in the survey design.

Chapter 4

Results and Discussion

4.1 Chapter Overview

A frequency analysis of participant demographics introduces the chapter. Researchers can comprehend sample characteristics more deeply by breaking them down by gender, age, marital status, education level, and job experience. Following the demographic survey, this chapter explains a reliability test that evaluates the measuring instrument's internal consistency using Cronbach's alpha. High dependability scores on psychological capital, family-supportive supervisory practices, and work performance provide credence to the study's premise. The KMO and Bartlett tests show that factor analysis can assess if a dataset may show correlations between variables. Community analysis contributes to our understanding of these determinants by emphasizing the critical roles that psychological capital and familial support play in successful career outcomes. Descriptive analysis is used to uncover the viewpoints of the participants, demonstrating agreement on the impact of psychological capital on work performance.

4.2 Interpretation of Survey Results

4.2.1 Frequency Analysis

Frequency distribution reflects the distribution of the participants on basis of their key demographics.

		Gender			Cumulative Percent
		Frequency	Percent	Valid Percent	
Valid	Male	79	52.7	52.7	52.7
	Female	71	47.3	47.3	100.0
	Total	150	100.0	100.0	

Table.4.1 Gender frequency

The above table shows the distribution of the participants on basis of their gender. It is evident that in the survey out of the 150 respondents, almost equal ratio of male and female were present making the study unbiased.

		Age			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	24-30 years old	27	18.0	18.0	18.0
	31-37 years old	90	60.0	60.0	78.0
	38-43 years old	33	22.0	22.0	100.0
	Total	150	100.0	100.0	

Table.4.2 Age frequency

The above table represents the distribution as per age, it is evident that almost 80% of the total participants are above 30 years of age which means they are mature and experienced enough to respond regarding the work family conflict.

		Marital status			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Married	61	40.7	40.7	40.7
	Unmarried	75	50.0	50.0	90.7
	Other	14	9.3	9.3	100.0
	Total	150	100.0	100.0	

Table.4.3 Marital Status frequency

The above table represents the distribution on basis of the marital status, it reflects that majority of the respondents are unmarried as 50% of the respondents are unmarried while others include married, divorced and widow etc. This represents the diverse opinions from the audience.

		Educational level			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Junior high school education or below	5	3.3	3.3	3.3
	Senior high school education	45	30.0	30.0	33.3
	College education	32	21.3	21.3	54.7
	Graduate education or above	68	45.3	45.3	100.0
	Total	150	100.0	100.0	

Table.4.4 Educational level frequency

The table above reflects that majority of the responses are coming from well-educated participants that is graduate or above, thus their responses will be sensible enough.

		Working experience			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1-3 years	2	1.3	1.3	1.3
	3-6 years	23	15.3	15.3	16.7
	7-10 years	74	49.3	49.3	66.0
	More than 10 years	51	34.0	34.0	100.0
	Total	150	100.0	100.0	

Table.4.5 Working Experience frequency

The above table represents the distribution on basis of the working experience, the majority of responses are from 7 years or more experience holders thus their experience can help in better reflecting upon their family conflicts and its impact on performance.

4.2.2 Reliability Test

Reliability tests, which are frequently evaluated using Cronbach's alpha, are crucial for determining the consistency and reliability of measuring instruments like surveys and questionnaires (Taber, 2018). How effectively a test or measurement tool yields

steady and consistent findings after several administrations is referred to as reliability in research and data analysis (Clark & Watson, 2019). Cronbach's alpha is a frequently used statistical measure to evaluate the internal consistency of a set of test items (Diedenhofen & Musch, 2016). It gives information on the overall dependability of the measurement and assesses the degree to which test items are related to one another. Higher levels of Cronbach's alpha, which range from 0 to 1, denote stronger internal consistency. Taber (2018) states that a value of 0.65 or more is thought to be the most suitable for any analysis.

Reliability Statistics	
Cronbach's Alpha	N of Items
.834	5

Table.4.6 Reliability Test

The above value of reliability is for the aspect of “Psychological capital – Work interfere family”, the value 0.834 confirms the model fitness and stronger reliability (Yue, et al., 2017). A higher Cronbach's Alpha value indicates a more reliable instrument, meaning that the test is better at capturing the true variation in the construct being measured, rather than random variability or measurement error.

Reliability Statistics	
Cronbach's Alpha	N of Items
.842	5

Table.4.7 Reliability Test

The above table of reliability is for “Family-Supportive supervisory behaviors - Family interfere work”, the reliability value of 0.842 represent the 84.2% of the instrument and model to be the best fit for analysis.

Reliability Statistics	
Cronbach's Alpha	N of Items
.823	4

Table.4.8 Reliability Test

The above table shows the reliability value of 0.823 for “Family member-report of target” that is again a good value for confirming reliability.

Reliability Statistics	
Cronbach's Alpha	N of Items
.813	4

Table.4.9 Reliability Test

The reliability of the above table for “Job performance” is again very good confirming 81% reliability of the instrument.

4.2.3 Factor Analysis

The factor analysis has been conducted in order to evaluate the overall correlation between the key variables been used in the model.

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.906
Bartlett's Test of Sphericity	Approx. Chi-Square	1207.496
	df	153
	Sig.	.000

Table.4.10 KMO and Bartlett

The current study employed the Kaiser-Meyer-Olkin test (KMO) and the Bartlett test (Surucu et al., 2022) to assess the suitability of the dataset for factor analysis and to examine the overall impact of the variables on the dependent variable. Hu et al. (2023) have discovered something intriguing in the data they examined. They discovered (2023) that they found a KMO scores of 0.906 2023, which is more than the normal significance threshold of 0.05. The data can be used for analysis of components since the variables are highly linked. Similarly, Nan et al. (2020) stated they found that the Bartlett test they performed showed statistically significant results. The variables that they examined have a major impact on the variables that affect the dependent. The KMO as well as the Bartlett tests proved that the study's data are suitable for analysis and provide the assurance that there is a meaningful connection among the variables studied of this research.

Communalities

	Initial	Extraction
My employment prevents me from dedicating time to my family member.	1.000	.590
Following work, I frequently find myself too fatigued to engage in activities with my family member.	1.000	.594
The hours I work disrupt the amount of time I can allocate to my family member.	1.000	.629
Upon returning home from work, I often lack the energy to fulfill the responsibilities of being a good family member.	1.000	.638
My extensive work commitments leave me with limited productivity for household tasks.	1.000	.632
It is challenging for me to perform my job well due to family-related factors.	1.000	.636
The responsibilities of my family life restrict the amount of time I can dedicate to work.	1.000	.593
Concerns about home affairs create difficulties for me in executing my job.	1.000	.677
Exhaustion from household responsibilities makes it challenging to muster the energy needed for my job.	1.000	.633
My family life positively contributes to my effectiveness as a worker.	1.000	.605

Table.4.11 Communalities

After the evaluation, it is discovered that both psychological capital and familial support significantly affect the work performance. This statement is supported by the communality values presented, in the range of 0.593% to 0.638%. Swain and Patoju (2022) underscored these findings as they demonstrate how these factors are instrumental in predicting overall job proficiency with their substantial explanatory study.

The following five statements regarding family support provide crucial perspectives that enhance our comprehension of accomplishing career success. These highlight the critical functions played by psychological capital and familial assistance in achieving occupational goals. The statistical findings presented here underscore the importance of these specific factors within the broader context of the study.

Communalities

	Initial	Extraction
My family member's job prevents him (her) from dedicating time to me.	1.000	.624
After work, my family member is frequently too fatigued to engage in activities with me.	1.000	.668
The working hours of my family member disrupt the time he (she) can spend with our children.	1.000	.713
When my family member returns home from work, there is often a lack of energy to fulfill the responsibilities of being a good family member.	1.000	.648
The actions that contribute to my effectiveness at work do not translate into improvements in my role as a family member	1.000	.568
The problem-solving approaches I employ at work lack effectiveness when applied to resolving issues at home.	1.000	.664
The behavior that proves effective and necessary for me at work would be counterproductive in a home setting.	1.000	.642
Because of the various pressures at work, there are times when I return home too stressed to engage in activities I usually enjoy.	1.000	.720

Extraction Method: Principal Component Analysis.

Table.4.12 Communalities

Consequently, similarities between the family reports and the last four job performance reports of the participants are carefully examined. Commonality values in published data, according to Chee and Sin (2020), vary from 0.624 to 0.720, which is regarded as a range that implies a robust explanation. A "community" in factor analysis is the portion of a variable's variation that can be accounted for by shared components. The stated range of 0.624 to 0.720 shows that these variables and the common components discovered are in good agreement. In a component analysis, a commonality near 1.0 suggests that the variables are mostly reflected in the underlying components (Floyd & Widaman, 1995). As a result, the variety of observed community values offers a significant and thorough explanation of the elements connected to family reports and work performance remarks.

Total Variance Explained						
Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	7.246	40.254	40.254	7.246	40.254	40.254
2	1.656	9.199	49.453	1.656	9.199	49.453
3	1.499	8.327	57.780	1.499	8.327	57.780

17	.275	1.530	98.640			
18	.245	1.360	100.000			

Table.4.13 Total Variance Explained

The above table reflects the variation in the components that cause the dependent variable change. The value of total variance is required to be 60% or above in order to be a good predictor, the value in above table is however diverse, its between 40% to 65% of range thus still reflecting moderate level of variation in the variables.

Total Variance Explained			
Component	Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %
1	3.134	17.409	17.409
2	3.065	17.026	34.436

Table.4.14 Total Variance Explained

The above table also reflects the variation from 17 to 63% where the 63% variation is a good sign.

	Component			
	1	2	3	4
My employment prevents me from dedicating time to my family member.	.582		.453	
Following work, I frequently find myself too fatigued to engage in activities with my family member.	.658			
The hours I work disrupt the amount of time I can allocate to my family member.	.623		.445	
Upon returning home from work, I often lack the energy to fulfill the responsibilities of being a good family member.	.575		.458	

a

Table.4.15 Component Matrix

In the above table, component represents the independent variables due to which the influence might be created or variation in variables can be observed. The table projects that for some of the statements like the last one “Upon returning home from

work...”, the component 1 and 3 are the cause of variation and these components are “Psychological capital” and “Family member – report of target”.

	Component			
	1	2	3	4
My extensive work commitments leave me with limited productivity for household tasks.	.675			
It is challenging for me to perform my job well due to family-related factors.	.564	.551		
The responsibilities of my family life restrict the amount of time I can dedicate to work.	.609	.455		
Concerns about home affairs create difficulties for me in executing my job.	.656	.444		
Exhaustion from household responsibilities makes it challenging to muster the energy needed for my job.	.610	.495		
My family life positively contributes to my effectiveness as a worker.	.616	.458		
My family member's job prevents him (her) from dedicating time to me.	.560			.406
After work, my family member is frequently too fatigued to engage in activities with me.	.613			
The working hours of my family member disrupt the time he (she) can spend with our children.	.705			

Table.4.16 Component Matrix

	Component			
	1	2	3	4
When my family member returns home from work, there is often a lack of energy to fulfill the responsibilities of being a good family member.	.720			
The actions that contribute to my effectiveness at work do not translate into improvements in my role as a family member	-.596			
The problem-solving approaches I employ at work lack effectiveness when applied to resolving issues at home.	-.686			
The behavior that proves effective and necessary for me at work would be counterproductive in a home setting.	-.696			
Because of the various pressures at work, there are times when I return home too stressed to engage in activities I usually enjoy.	-.641			.506

Extraction Method: Principal Component Analysis.

a. 4 components extracted.

Table.4.17 Component Matrix

The above table also reflects that majority of the influence is because of the component of psychological capital.

Rotated Component Matrix				
	Component			
	1	2	3	4
My employment prevents me from dedicating time to my family member.		.724		
Following work, I frequently find myself too fatigued to engage in activities with my family member.		.646		
The hours I work disrupt the amount of time I can allocate to my family member.		.736		
Upon returning home from work, I often lack the energy to fulfill the responsibilities of being a good family member.		.766		
My extensive work commitments leave me with limited productivity for household tasks.		.693		
It is challenging for me to perform my job well due to family-related factors.	.748			
The responsibilities of my family life restrict the amount of time I can dedicate to work.	.715			
Concerns about home affairs create difficulties for me in executing my job.	.730			
Exhaustion from household responsibilities makes it challenging to muster the energy needed for my job.	.751			
My family life positively contributes to my effectiveness as a worker.	.722			

Table.4.18 Rotated Component Matrix

The above table reflects the Pearson correlation between items of the questionnaire and they tell which item explains which component. The table above shows that the first 5 statements explain the second component that is “Family support supervisory” while the next 5 explain the psychological capital.

	Component			
	1	2	3	4
My family member's job prevents him (her) from dedicating time to me.				.755
After work, my family member is frequently too fatigued to engage in activities with me.				.761
The working hours of my family member disrupt the time he (she) can spend with our children.				.741
When my family member returns home from work, there is often a lack of energy to fulfill the responsibilities of being a good family member.				.638
The actions that contribute to my effectiveness at work do not translate into improvements in my role as a family member			.684	
The problem-solving approaches I employ at work lack effectiveness when applied to resolving issues at home.			.702	
The behavior that proves effective and necessary for me at work would be counterproductive in a home setting.			.662	
Because of the various pressures at work, there are times when I return home too stressed to engage in activities I usually enjoy.			.794	

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.
a. Rotation converged in 6 iterations.

Table.4.19 Rotated Component Matrix

The table above similarly shows that the first 4 statements explain the 4th component that is the “job performance” while the last four statements explain the variation in “family member report to target”.

Component Transformation Matrix				
Component	1	2	3	4
1	.515	.518	-.491	.474
2	.845	-.428	.276	-.163
3	.138	.728	.378	-.555
4	-.044	.134	.735	.664

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.

Table.4.20 Component transformation matrix

The above table explains the overall correlation been explained by each of the four components been used in the study.

4.3 Descriptive Analysis

Descriptives		Statistic	Std. Error
Psychological capital - Work interfere family	Mean	2.4613	.06980
	95% Confidence Interval for Lower Bound	2.3234	
	Mean	Upper Bound	2.5992
	5% Trimmed Mean	2.4341	
	Median	2.4000	
	Variance	.731	
	Std. Deviation	.85482	
	Minimum	1.00	
	Maximum	4.80	
	Range	3.80	
	Interquartile Range	1.20	
	Skewness	.509	.198
	Kurtosis	-.185	.394
Family-supportive supervisory behaviors - Family interfere work	Mean	3.0853	.07392
	95% Confidence Interval for Lower Bound	2.9393	
	Mean	Upper Bound	3.2314
	5% Trimmed Mean	3.0941	
	Median	3.0000	
	Variance	.820	
	Std. Deviation	.90527	
	Minimum	1.20	
	Maximum	5.00	
	Range	3.80	
	Interquartile Range	1.20	
	Skewness	-.146	.198

Table.4.21 Descriptive Statistics (a)

Important details on participant perceptions of psychological capital and its relationship to work performance are provided by the results displayed in the descriptive statistics table. The mean score of 2.4613 indicates the widespread agreement among the respondents with the remarks suggesting the impact of psychological capital on job performance. This indicates that a sizable percentage of participants are cognizant of the influence psychological capital has on their professional success. On the other hand, the mean score of 3.0 indicates a distinct pattern when looking at the assertions about job interference, family support, and supervisory conduct. The findings show that a sizable percentage of respondents provided ambiguous or neutral responses.

In other words, most participants showed no clear tendency to agree or disagree with statements regarding supervisory behavior, family support, and work-related interference.

Descriptives		Statistic	Std. Error
Family member-report of target	Mean	2.5217	.07110
	95% Confidence Interval for Lower Bound	2.3812	
	Mean Upper Bound	2.6622	
	5% Trimmed Mean	2.4944	
	Median	2.5000	
	Variance	.758	
	Std. Deviation	.87082	
	Minimum	1.00	
	Maximum	4.75	
	Range	3.75	
	Interquartile Range	1.25	
	Skewness	.422	.198
	Kurtosis	-.366	.394
Job performance	Mean	3.6817	.06796
	95% Confidence Interval for Lower Bound	3.5474	
	Mean Upper Bound	3.8160	
	5% Trimmed Mean	3.7111	
	Median	3.7500	
	Variance	.693	
	Std. Deviation	.83239	
	Minimum	1.50	
	Maximum	5.00	
	Range	3.50	
	Interquartile Range	1.50	
	Skewness	-.374	.198

Table.4.22 Descriptive Statistics (b)

Similarly, the data in the preceding table indicates that families report an average aim of 2.5. This score shows that respondents vacillate between neutral behavior and agreement, with a tendency to agree with the assertion to some extent. On the other hand, the mean value obtained while assessing work performance was 3. 6, falling inside the disagreement range. This indicates that a sizable percentage of respondents don't agree with the job performance claims. These findings suggest that family members' opinions of the target individual differ from assessments of the employee's work performance.

4.4 Test of Normality

Tests of Normality						
	Kolmogorov-Smirnov ^a			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Psychologicalcapital - Work interfere family	.100	150	.001	.968	150	.001
Family-supportive supervisory behaviors - Family interfere work	.076	150	.034	.980	150	.028
Family member-report of target	.102	150	.001	.970	150	.003
Job performance	.099	150	.001	.964	150	.001

a. Lilliefors Significance Correction

Table.4.23: Test of Normality

When evaluating the general normality of the data for ensuing null hypothesis testing, the Kolmogorov-Smirnov test results are a crucial resource. A predefined alpha value of 0.05 is used to compare the significance (sig) findings from normality tests (Sari et al., 2021). The results indicates that all of the key values are lower than the threshold alpha value. This implied that the results is less than 5 %, meanings the data obtained follow the trend of normal distribution. The small value of p-value means there is a rejection of the null hypothesis. Hence justify the statement that the statistical analysis is reliable and reinforces the model's dependability for this research.

4.5 Correlation Analysis

The value of Pearson coefficient, which ranging from -1.0 to +1.0, is a useful tool in determining the strength and the direction of the relationship among variables. A negative value of Pearson coefficient implies that there is an inverse relationship, which means the increase in one variable is related to a decrease in the value of the other variable. On the other hand, a positive coefficient tell the researches that there is a direct relationship among the variables, where both variables move in a same direction. In other scenario, when the coefficient is 0, indicates that there is no significant correlation between the variables. Hence, through the interpretation of the value of coefficients, researchers can recognize the patterns and relationship of the data collected, and provide a clear picture about the relationship between different variables.

Correlations				
		Psychologicalcapital - Work interfere family	Familysupportiv e supervisory behaviors - Family interfere work	Family member-report of target
Psychologicalcapital - Work interfere family	Pearson Correlation	1	.478**	.508**
	Sig. (2-tailed)		.000	.000
	N	150	150	150
Family-supportive supervisory behaviors - Family interfere work	Pearson Correlation	.478**	1	.501**
	Sig. (2-tailed)	.000		.000
	N	150	150	150
Family member-report of target	Pearson Correlation	.508**	.501**	1
	Sig. (2-tailed)	.000	.000	
	N	150	150	150
Job performance	Pearson Correlation	-.554**	-.491**	-.617**
	Sig. (2-tailed)	.000	.000	.000
	N	150	150	150

Table.4.24 Correlation Analysis

Overall, the robust and moderate correlations between variables in this study indicates that the variables are interdependent and affect each other in meaningful ways. The negative correlation between the variable of work performance and family support, emphasizes the importance of keeping a balance between work and family affairs. Through interpreting these relationship, researchers can develop more useful decision and strategies to manage these variables in a more effective manner. Correlation analysis is a valuable tool to provide insights for researchers to learn the complex interplay between the variables and can help researchers to make decision in various scenario, related to work and personal life.

Correlations		Job performance
Psychological capital - Work interfere family	Pearson Correlation	-.554 **
	Sig. (2-tailed)	.000
	N	150
Family-supportive supervisory behaviors - Family interfere work	Pearson Correlation	-.491 **
	Sig. (2-tailed)	.000
	N	150
Family member-report of target	Pearson Correlation	-.617 **
	Sig. (2-tailed)	.000
	N	150
Job performance	Pearson Correlation	1
	Sig. (2-tailed)	
	N	150

**. Correlation is significant at the 0.01 level (2-tailed).

Table.4.25 Correlation Analysis

Moreover, the extent of these negative correlations, with the value ranging from -0.491 to -0.617, signifies that a significant part of the relationship between the variables of work performance and other variables can be explained. For example, the -0.617 correlation between work performance and work stress indicates that there are approximately 38 % of the work performance will be affected by work stress. This emphasizes the importance of dealing with work stress in order to perform better in work. The justifications that these aspects have a negative correlation with word performance is strengthen by the fact that the negative correlation applies for all other four variables. These findings help identify potential factors impacting work performance in the examined setting by providing insightful quantitative information about the particular nature of the interactions.

Nonparametric Correlations

		Correlations	
		Psychological capital - Work interfere family	Family supportive supervisory behaviors - Family interfere work
Spearman's rho	Psychological capital - Work interfere family	Correlation Coefficient	1.000
		Sig. (2-tailed)	.513**
		N	.000
		150	150
	Family-supportive supervisory behaviors - Family interfere work	Correlation Coefficient	.513**
		Sig. (2-tailed)	1.000
		N	.000
		150	150
	Family member-report of target	Correlation Coefficient	.580**
		Sig. (2-tailed)	.532**
		N	.000
		150	150
	Job performance	Correlation Coefficient	-.593**
		Sig. (2-tailed)	-.513**
		N	.000
		150	150

Table.4.26 Non parametric Correlation Analysis

The correlation test is a non-parametric statistical method that is used to clarify the relationships between variables without requiring a normal distribution. Interestingly, a trend that is in line with previous findings is observed, in which work success and family support continue to have an adverse connection. On the other hand, there is a positive connection seen between the remaining factors and work performance, meaning that a gain in one variable usually results in an increase in the other. Because a non-parametric test does not make any particular distributional assumptions, it emphasizes the validity of the associations that have been found. These findings provide a more nuanced understanding of the complex interactions between many variables and job performance in the research, enabling a more thorough interpretation of the dynamics that were seen.

Correlations			Family member-report of target	Job performance
Spearman's rho	Psychological capital - Work interfere family	Correlation Coefficient	.580**	-.593**
		Sig. (2-tailed)	.000	.000
		N	150	150
	Family-supportive supervisory behaviors - Family interfere work	Correlation Coefficient	.532**	-.513**
		Sig. (2-tailed)	.000	.000
		N	150	150
	Family member-report of target	Correlation Coefficient	1.000	-.635**
		Sig. (2-tailed)	.	.000
		N	150	150
	Job performance	Correlation Coefficient	-.635**	1.000
		Sig. (2-tailed)	.000	.
		N	150	150

** . Correlation is significant at the 0.01 level (2-tailed).

Table.4.27 Non parametric Correlation Analysis

The presented table further illustrates that even in the absence of a normal distribution, the variables continue to exhibit a discernible negative association. Despite the absence of a normal distribution, a clear correlation persists among the components, indicating a meaningful relationship between them. This suggests that the presence of a normal distribution is not a prerequisite for the observed associations, emphasizing the robustness of the identified relationships between the variables.

4.6 Chapter Summary

Frequency analysis, which demonstrates that the gender distribution of the 150 respondents is balanced, assures the study's neutrality. The majority of the participants are over 30, mature, and experienced, and they provide thoughtful input on work-life problems. The distribution of respondents' job experience reveals that most replies are from those with at least seven years of experience, despite the fact that respondents' marital status and educational attainment are diverse. This improves the survey's dependability. Cronbach's alpha is then used in this chapter to examine reliability, and the results indicate strong internal consistency for a number of variables, such as work performance, psychological capital, and supervisory behaviors that assist families.

Factor analysis confirms the relevance and usefulness of the dataset in clarifying the relationships between the variables assessed by the Bartlett test and the KMO test.

Communalities analysis indicates the substantial contribution of psychological capital and family support to explaining job performance. Descriptive analysis offers insightful information on the viewpoints of participants. Although there is agreement in this literature about the impact of psychological capital, it also poses concerns regarding family support and job success. The dataset is deemed eligible for additional analysis by a normality test at the conclusion of the chapter, and a correlation analysis offers both parametric and non-parametric insights into the correlations between variables and Acquire a thorough comprehension of interactions.

Chapter 5

Findings and Results Summary

5.1 Chapter Overview

The conclusion highlights stressors and unique generational characteristics, highlighting the challenges posed by increased female labor force entry. This study lays the foundation for an in-depth investigation of the effects of psychological capital, supervisor support, and family perspectives on job performance. This method adopts a positivist stance that supports a quantitative approach to retailing, while recognizing potential biases and limitations in sampling representation. The purpose of the recommendations is to improve the robustness of future research by recommending mixed methods approaches, clear role importance measures, broader applicability, and diverse samples.

5.2 Expected Outcome and Actual Finding

The goal of this study is to clarify the complex dynamics surrounding work-family conflict among Chinese workers in the generations that followed the 1980s and 1990s. The report highlights the growth in women's employment engagement and the resulting problems of combining varied jobs by providing a thorough analysis of the last ten years. There are several noteworthy aspects that contribute to role conflict, such as job schedules, family size, and childcare obligations. The theme of stress becomes evident, encompassing its behavioral, psychological, and physical expressions as people attempt to balance the responsibilities of their personal and professional lives. The post-1980s and post-90 generation is characterized in a way that emphasizes their specific qualities, including a strong drive for personal achievement, a self-centered mindset, and a different take on work-related values. The goals of the study open the door to a thorough examination of how family perspectives, psychological capital, and supervisor support for families affect workers' productivity on the workplace. Aiming to offer insights that might help design

successful management strategies, the study is conducted against the competitive background of China's workforce.

Clearly outlined, the study questions and aims offer a strong basis for further empirical investigation. Besides, the result findings of the research showed a great implications for individuals. Since there is a negative correlations among the job performance and the job-related aspects such as work stress, work overload and family support, individuals can implement strategies to tackle these factors and enhance their job performance. For example, reduce the work stress by seeking family support. Moreover, individuals can reassign the tasks and delegate the responsibilities to manage the workload in a more effective way. The way of stress coping is very crucial for people nowadays, as the mental health illness is become more and more common.

This study also provide the insights regarding to the relationship between the work family conflict and the work performance, by understanding the negative correlation among the variables and work performance, company can apply the strategies to remove or lower down the negative impact of the work-family conflict on work performance, to further enhance the job satisfaction and increase the productivity. This study also highlights the importance of dynamic nature of resource allocation and identifying the areas for improvement in overall well-being of employees. Companies can built a positive work-life relationships and improve the employee engagement. To thoroughly understand the impact of work-family connections on individuals, the study considers three key elements: job performance, psychological capital (inner resources), and supportive family supervisory behaviors (Crain et al., 2019). Addressing work-family conflicts becomes crucial for improving overall well-being, as they negatively affect the productivity of Chinese workers from the post-1980s and post-1990s generation.

When analyzing work-life conflict and job satisfaction in the retail sector, a positivist perspective that prioritizes quantitative methodologies and disapproves of qualitative approaches due to reliability problems is suitable (Setiawan et al., 2020). After that, the study methodology is covered in this work, with a particular emphasis on variance control as a strategy for maintaining internal validity. Descriptive research is being thoroughly examined, with an emphasis on its many uses, such as highlighting traits,

providing brief summaries, identifying connections, and answering contemporary issues (Glasofer & Townsend, 2020).

A few ontological and epistemological positions are explained in the research philosophy part by the positivism and interpretivism sections. The quantitative design used for data gathering is consistent with the positivist understanding of the research process. To achieve good representative of the population, the study strategy is quite thorough and prioritizes probability sampling with stratified random sample (Mohajan, 2020). It is stressed that in order to guarantee internal validity and reliability, research must be well designed. The research site is focuses on the Chinese environment and uses surveys dispersed across many platforms to target professionals from the post-1980s and post-1990s generations. Using a positive approach and quantitative research methods, the methodology research offers a strong framework for the study, integrating theoretical foundations with real-world considerations to explore work-life conflict and job satisfaction in the Chinese retail sector.

5.3 Limitations

In line with typical studies, limitations are evident in the present study concerning the sample, measures, and analyses. The sample is limited to a certain area of China and is not randomly selected. But unlike studies that just looked at one company or kind of work, the sample selection in the study includes a wide variety of jobs from different organizations, which is a step up from previous studies that only looked at families with high levels of education.

In order to explain gender variations, assumptions were made about the relevance of the family role, even though role importance or centrality was not tested specifically. The chosen measures are appropriate, even if they might not be the most contemporary organizational science scales. The questions in the Work-Family Conflict (WFC) scale are consistent with previous measures; they include disruptions of time or effort and specifically address the effects on partners or kids (Zhang & Bowen, 2021). This option was better than scales that ask ambiguous questions regarding "family." Some could suggest using the pair as the unit of study and more

recent techniques like hierarchical linear modeling. The results of this study help to support this approach, but more complex analyses were not required to achieve the study's goal of forecasting individual job satisfaction based on personal and occupational attributes.

Furthermore, the investigation of complex and context-specific elements that may affect work-life conflict and job satisfaction may be hampered by the only reliance on a positivist viewpoint and quantitative methodologies (Leeming, et al., 2017). When qualitative approaches are eliminated, significant insights into unique experiences and viewpoints may be lost. Moreover, while self-administered surveys prove useful in collecting extensive data, their dependence on participant self-reports may introduce response bias and social desirability effects, thereby limiting the scope of the study (Williams, 2015). The findings of this study are not universally applicable, due to the geographical restriction at the region of China. On the other hand, the employment of hiding age category for the data analysis can smoothen the analysis process, however, it possess potential risk which may neglect the significant generational differences which may affect the conclusions of the study. It is important to consider the unique background, experiences and characteristics of each generations while conducting the research. In order to solve this issue, the study should use pseudonyms to protect the provacy of the participants, while at the same time, allow external stakeholders and examiners to evaluate the findings. This will ensures the ethical integrity of the study and accurate representation of the sample.

5.4 Implication

Findings of this study have indicates that family support and psychological aspects have greatest impact on the overall job performance. Hence, in order to improve the job performance, organizations is advised to consider to implement the practice which can increase the psychological capital and provide family-freindly assistance (Mishra, et al., 2019). This research have enlighten the importance of support from supervisors in motivating creative work practices among employees. Supervisors should establish orientation programme, which will enhance their ability to react promptly to creatuve work methods that workers showcase (Clark, et al., 2019).

Supervisors is also suggested to actively identify and praise creative work practices, to act as a role model for their colleagues. They should lead a brainstorming sessions during meetings, to generate creative ideas. Supervisors is advised to provide an atmosphere that enhance creativity, encourage unrestricted communications and promises convinient access to essential resources (Chin, et al., 2021).

Sjodin et al. (2020) highlighted the challenges in recognizing and coordinating the most suitable persons for innovations at the upper level of management. This research recommended that psychological capital should be taken account as an important factor when choosing the right workers for a certain job positions, which need creativity in problem solving. This strategy will match the qualifications of qualified candidates with the job needs. The study raises the idea of creating training programs to improve the competences required for encouraging creative work behavior in addition to selection. It is recommended that organizations concentrate on HR procedures, such as creating a positive work environment, granting employees autonomy, and matching the compensation plan to creative job output.

Even though it was carried out in a Chinese cultural setting, the current study advances knowledge about Chinese workers' demands and perspectives. Similar to the importance placed on families in Chinese culture, family relationships are highly valued in Chinese society (Han, 2012). Thus, in family-oriented cultures such as China, firms must to acknowledge the significance of the family unit in addition to strategically developing individuals through organizational interventions (Kossek, et al., 2012). It is advised that meetings be held between the company and the families of employees to create win-win agreements. For example, it might be advantageous to designate an HR executive to oversee a group of families and give them the task of organizing regular meetings to discuss their issues. These treatments foster creative work practices in addition to helping people grow personally. For individuals who are interested in learning more about the cultural background of China and the elements that influence innovative work behavior, this research provides insightful information.

5.5 Chapter Summary

The research digs into the complicated connections between doing a good job and feeling mentally good for these workers. It looks at how family support and company's supervisor on job performance of the workers themselves. The main goal is to give useful ideas that can help make good management plans in this tough situation. The study shows how well-being of workers being enhance through the balancing of work and family, which is a personal aspects and really affects outcomes like being happy at work, sticking with the job, and being creative. It connects this to the Personal Resource Allocation (PRA) idea, which looks at managing resources like needs, personal outcomes, ways of sharing, and personal stuff.

To get what happens with work and family, the study talks about things like Job Performance, Family-Supportive Supervisory Behaviors-Family Work Conflict, and Psychological Capital-Work Family Conflict. These ideas show how having problems with work and family hurts the ability of Chinese workers born after the 1980s and 1990s to do well at work. The part about how the study was conducted is providing a robust foundation, makes a strong base, saying that using numbers and looking at things positively is the way to go to understand the conflict between work and life and feeling good about the job in the Chinese workforce nowadays. The survey results show that the tool used is good and gives a fair picture of the different kinds of people. Looking at the factors shows how important psychological capital and family support are for understanding why people do well at work. The study says it has limits by talking about the sample and how there might be problems in what people say. Just looking at the retail business in China might make it hard to say things about everyone, and only looking at things in a positive way and using numbers might make it hard to see the small stuff. For later studies, the paper studied the use of lots of different groups, look at specific roles, and use different ways of figuring things out. In the end, this study gives good info about how work and family conflicts work and has ideas for making future studies better for all kinds of people and situations.

Chapter 6

Recommendations, Conclusions and Further Research

6.1 Recommendations

With the intention to improve the external validity for further studies, researcher is suggested to investigate the work life conflict and work performance in particular organizational contexts, rather than select the sample randomly (An, et al., 2020). For instance, small businesses, non-profit organizations, and multinational corporations. This will deliver a deeper understanding of the mechanism between work-life conflict affecting the work performance in different organizational settings.

On the other hand, researcher is suggested to study the impacts of work-life conflict on job performance in different industries contexts. For example, healthcare industry, financial sector and even educational contexts. This assures the consideration of industry-related aspects in studying the impacts of work-life conflict and work performance. To obtain the ever-changing nature of work-family conflict, future researchers are advised to employ longitudinal study method (Bouwmeester, et al., 2021). This kind of research will track the respondents over a fixed timeframe, which will allow a better understanding of how perceptions and experiences of individuals evolve over time. Other than the key variables analyzed, there may be other underlying factors affecting the work-family conflict that were not included in the current model. Conducting exploratory factor analysis with a broader set of variables could uncover the correlations.

In a nutshell, with the increasing of sample size, increase the validated instrumentation, use mixed methods, employment of advanced analytical techniques, and broaden the research context to other industries contexts, future studies could provide a more holistic understanding regarding the complex relationship between work-life conflict and job satisfaction. These improvements will enhance the reliability and generalizability of the results.

6.2 Conclusion of Key Findings

To summarize, the comprehensive investigation of the survey data has provided meaningful knowledge on the complicated nature of work-family conflict and how it affects job performance. The normality of the research was studied, by the conduction of frequency analysis, which revealed a gender distribution among the 150 respondents that was well-balanced. The vast majority of participants, who were mainly over 30 years old and came from a different educational and marital situations, showed a depth of experience that made their opinions on work-family issues seem more credible. The internal consistency of important variables including work performance, psychological capital, and family-supportive supervisory behaviors was highlighted by reliability tests that evaluated using the Cronbach's alpha. The Bartlett and KMO tests corroborated the factor analysis's findings about the importance and dependency of these factors. The significant roles that psychological capital and family support play in determining occupational success were confirmed by a communities study.

Varied viewpoints on participant perceptions were revealed using descriptive analysis, which also revealed broad consensus about the impact of psychological capital on work performance. The intricacy of these issues was highlighted by the vagueness and neutral answers seen in relation to claims about family assistance, work-related interference, and supervisory conduct. The model's dependability for this research was reinforced by the test of normalcy, which validated the statistical analysis's dependability. Both parametric and non-parametric correlation studies revealed strong and moderate connections between the variables, pointing to their interdependence. The significance of striking a balance between work and family matters was underscored by noteworthy negative correlations found between work performance and factors such as family support.

These results advance our knowledge of the complex relationships between the several elements affecting work performance. The study emphasizes the significance of taking a balanced approach to work and personal life and offers a basis for well-informed decision-making and strategy formulation. All things considered, the study deepens our understanding of the complex dynamics of work-family conflict and the

effects it has on people in a range of professional contexts. The survey's results provide a comprehensive picture of the participants' demographics, demonstrating that participants' marital and educational backgrounds are diverse, that gender is properly represented, and that the age group is predominantly mature (80% of respondents are over 30). The reliability test, assessed using Cronbach's Alpha, validates the consistency and dependability of the survey instrument with results much above the recommended level. A factor analysis demonstrates the significant contributions that familial support and psychological capital make to the explanation of variations in professional performance. Descriptive analysis highlights the opinions of the participants, revealing agreement on the influence of psychological capital on job performance but disagreement in responses concerning family support. The normality test findings confirm that the data are suitable for additional investigation. The results of correlation analysis, which makes use of non-parametric tests and Pearson coefficients, show moderate to strong inter-correlations between the variables and a consistent negative relationship between job performance and family support. Taken together, the results provide light on the dynamics of work-family conflict, demonstrating the strength of the connections that have been noted and setting the stage for more nuanced interpretations within the confines of the research.

Young parents who were born in the 1980s and 90s may see job performance as a trade-off for flexible schedules, capacity, and the chance to balance work and family life because of certain characteristics. They may be willing to put up with subpar work output if it means achieving something they value more. Rather of putting their jobs first, they usually prioritize the education of their children.

Over the duration of their employment, supervisory authorities ought to deepen their comprehension of workers' roles in their personal and professional lives. The creation of efficient two-way channels of communication makes it possible to gather important data on the difficulties academics have in their personal and professional life. The Chinese government is working to bring universities up to par with international norms. As such, it is critical that businesses take proactive measures to address academic engagement so that they may improve performance without sacrificing their commitment to their families. Achieving a perfect balance between work and family life is essential for real performance. The results of the study pointed that by putting

supportive workplace policies in workplace, organizations may improve the well-being of their workers and their families. Notably, establishing family-friendly policies is important to create a conducive environment at work where employees' families are taken care of.

6.3 Future Scope of Study

It would be meaningful if future researchers take into account of other aspects, which may affects the relationship between the work-family conflict and job performance. By considering the aspects like socioeconomic level, and cultural background, may provide a more thorough knowledge of the variables impacting job performance.

Future researchers could increase the sample size, for the sake of producing a more robust results, which comprised of a more representative amount of dataset, and broadly related to research by employing random sampling technique throughout a wide range of contexts and different geographical areas. Besides, to deepen the comprehension of the relationship between work-life conflict and working performance among Chinese employees, it would be useful for future research to investigate the impact of other related cultural values, such as collectivism and Confucianism. The unique cultural background of China may influence the perspectives of the respondents on and mechanism to work-life conflict and work performance.

Considering the variations of marital situations, more research into the mechanism regarding to how various marital statuses influence aspects of work-family conflict might be meaningful. To understand the distinctive experiences of married, divorced, or widowed people, a qualitative investigation may be necessary. Complex correlations between variables are hinted at by the correlation analysis. Subsequent research endeavors may undertake a more comprehensive analysis, taking into account plausible moderating or mediating elements that may impact the detected associations. Adding to the body of knowledge would be the discovery of these connections' internal workings and external expressions. In the end, these study

findings may be usefully incorporated into management procedures, thus enhancing the body of knowledge about job, family, and personal well-being.

6.4 Chapter Summary

In Chapter 6, the researchers' thorough examination of the effects of work-life conflict on job performance is presented, along with incisive recommendations, findings, and ideas for future research. It is suggested that work-life conflict and performance be examined in certain organizational contexts, such as small enterprises, non-profit organizations, and multinational corporations, in order to take a more focused approach to future research. Furthermore, it is stressed how crucial it is to investigate the impact of work-life conflict across a variety of areas, such as healthcare, banking, and education. Expanding sample sizes, using instruments that have been verified, using mixed methodologies, and using sophisticated analytical approaches are some of the improvements that are suggested to deepen our understanding of the intricate link between job satisfaction and work-life conflict. A summary of the major findings is provided at the end of the chapter, emphasizing the participants' diversified demographics, gender distribution that is well-balanced, and the complex relationship between psychological capital and work success. The study's future scope is finally outlined, with recommendations for factors like socioeconomic status and cultural background to be explored, sample sizes to be increased for wider applicability, and a thorough examination of how marital status may affect perceptions of work-family conflict. It is recommended that intricate linkages be examined in detail in order to gain a thorough knowledge that will guide efficient management techniques and advance current theoretical studies on the relationships between job, family, and personal well-being.
